

DISPLAY UTILIZING CHOLESTERIN LIQUID CRYSTAL
POLYMER FOR ENHANCING CONTRAST

BACKGROUND OF THE INVENTION

5

The present invention is related to a display utilizing cholesterin liquid crystal polymer for enhancing contrast, and more particularly to a display with self-luminous cell. The display includes a lighting layer having cholesterin liquid crystal phase. The lighting layer goes through 10 backfire and is arranged into planer structure to induce and emit manual circular polarized light. The lighting layer cooperates with a circular polarizing optical coating to enhance the contrast and brightness of the display.

15 The conventional lightweight and small-sized display with self-luminous cell has wider vision angle. Such display can be made on a soft substrate. Fig. 5 shows the structure of the self-luminous cell. An ITO bus-bar 81 is overlaid on a transparent substrate 8. An electric hole conductive layer 82 is overlaid on the ITO bus-bar 81. A lighting layer 83 20 is overlaid on the electric hole conductive layer 82. An electronic conductive layer 84 is overlaid on the lighting layer 83. A cathode electrode layer 85 is overlaid on the electronic conductive layer 84. An insulating packaging layer (not shown) is disposed on the cathode electrode layer 85. When a circuit supplies driving current to the display, 25 by means of the lighting layer 83, the self-luminous cell emits light.

The cathode electrode layer 85 is a metal layer forming a mirror

face that tends to reflect the incident light A of the environment as shown in Fig. 6. Accordingly, when the display panel is used outdoors in brighter environment, the cathode electrode layer 85 will reflect the incident light to form environmental reflected light B. The reflected light

5 B will interfere with and affect the displaying effect of the display panel. To solve this problem, generally a black cathode is used. Alternatively, a black layer is disposed between the cathode electrode layer 85 and the lighting layer 83 for absorbing light. Still alternatively, a quarter wavelength phase difference plate or circular polarizing optical coating is

10 laid on the cell to eliminate the interference of the light reflected by the cathode electrode layer 85. However, the reliability of the black cathode will decline with time. With respect to the black layer, the development of the material and practical effect of such material have not yet matured. The phase difference plate utilizes light travel difference of the reflected

15 light to destructively interfere with and eliminate the light. Such measure requires precise control of the distance between the phase difference plate and the cathode electrode layer 85 for eliminating the reflected light. It is quite difficult to perform the manufacturing procedure. Moreover, such measure can hardly cover all visible light wavelengths.

20

In addition, with respect to the circular polarizing optical coating, the manual circular polarized light in one direction (such as levorotary light) of the environmental incident light will be absorbed by the circular polarizing optical coating, while the manual circular polarized light in

25 another direction (such as dextrorotary light) of the environmental incident light is permitted to penetrate through the circular polarizing optical coating. The penetrating dextrorotary light is reflected by the

cathode electrode layer 85 to form levorotary light. When passing through the circular polarizing optical coating, the reflected levorotary light will be further absorbed by the circular polarizing optical coating. Therefore, the cathode reflection interference of the environmental
5 intense light will be eliminated. However, the circular polarizing optical coating will absorb the manual circular polarized light in one direction of the incident light. Therefore, in general, 50% of the light emitted from the self-luminous cell will be also absorbed so that the brightness of the self-luminous cell will be half reduced. This greatly reduces the using
10 efficiency of energy.

SUMMARY OF THE INVENTION

It is therefore a primary object of the present invention to provide a
15 display utilizing cholesterin liquid crystal polymer for enhancing contrast. When using the display outdoors in a brighter environment, the circular polarizing optical coating will first absorbs the incident levorotary light of the environmental incident light and permits the incident dextrorotary light to penetrate through. The penetrating incident dextrorotary light is
20 reflected by the cathode electrode layer to form reflected levorotary light. When the reflected levorotary light passes through the circular polarizing optical coating, the reflected levorotary light is further absorbed by the circular polarizing optical coating. Therefore, the cathode reflection interference of the intense light of the environment will be eliminated to
25 enhance the contrast of the display under intense light of the environment. The manual circular polarized dextrorotary light emitted from the lighting layer will not be absorbed by the circular polarizing optical

coating and can totally penetrate through the circular polarized optical coating to enhance the brightness of the display. Accordingly, the using efficiency of the energy is increased and the contrast and brightness of the display are greatly enhanced.

5

According to the above object, the display includes a transparent substrate and a transparent bus-bar overlaid on the substrate. An electric hole conductive layer is overlaid on the bus-bar. At least one lighting layer is overlaid on the electric hole conductive layer. An electronic conductive layer is overlaid on the lighting layer. A cathode electrode layer is overlaid on the electronic conductive layer. An insulating packaging layer is disposed on the cathode electrode layer. The electric hole conductive layer is painted with polymer electric hole conductive material and coordinated on the bus-bar. The lighting layer has 10 cholesterin liquid crystal phase and is made on the coordinated electric hole conductive layer. The lighting layer goes through backfire to be arranged into such a structure that the cholesterin liquid crystal lighting molecules can induce and emit manual circular polarized light. A circular 15 polarizing optical coating is attached to one face of the substrate.

20

The present invention can be best understood through the following description and accompanying drawings wherein:

BRIEF DESCRIPTION OF THE DRAWINGS

25

Fig. 1 is a diagram showing the structure of the present invention; Fig. 2 shows the lighting layer of the present invention, which has

cholesterin liquid crystal phase;

Fig. 3 shows that the lighting layer of the present invention goes through backfire and is arranged into planer structure to emit dextrorotary light;

5 Fig. 4 shows that the cathode reflection interference is eliminated and the brightness is enhanced;

Fig. 5 shows the structure of a conventional display; and

Fig. 6 shows the cathode reflection interference of the conventional display.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Please refer to Figs. 1 to 3. The present invention provides a display utilizing cholesterin liquid crystal polymer for enhancing contrast.

15 The display includes a transparent substrate 1 and a transparent bus-bar 2 overlaid on the substrate 1. In this embodiment, the substrate 1 is a glass substrate and the bus-bar 2 is an ITO bus-bar. An electric hole conductive layer 3 is overlaid on the bus-bar 2. At least one lighting layer 4 is overlaid on the electric hole conductive layer 3. An electronic conductive layer 5 is overlaid on the lighting layer 4. A cathode electrode layer 6 is overlaid on the electronic conductive layer 5. An insulating packaging layer (not shown) is disposed on the cathode electrode layer 6. When a circuit supplies driving current to the display, by means of the lighting layer 4, the display emits light.

25

The electric hole conductive layer 3 is painted with polymer electric hole conductive material and coordinated on the bus-bar 2. In this

embodiment, the polymer electric hole conductive material is discotic liquid crystals. The electric hole conductive layer 3 is directionally rubbed to have ability to coordinate. The lighting layer 4 has cholesterin liquid crystal phase and is made on the coordinated electric hole 5 conductive layer 3 of discotic liquid crystals. The lighting layer 4 goes through backfire to be arranged into planer structure, whereby the cholesterin liquid crystal lighting molecules can induce and emit manual circular polarized light. In addition, a circular polarizing optical coating 7 is attached to one face of the substrate 1. In this embodiment, the lighting 10 layer 4 emits dextrorotary light and the circular polarizing optical coating 7 is attached to the face of the substrate 1 from which the light goes out.

Referring to Fig. 4, when using the display outdoors in a brighter environment, the circular polarizing optical coating 7 will first absorb the 15 incident levorotary light of the environmental incident light C and permit the incident dextrorotary light C1 to penetrate through. The penetrating incident dextrorotary light C1 is reflected by the cathode electrode layer 6 to form reflected levorotary light C2. When the reflected levorotary light C2 passes through the circular polarizing optical coating 7, the 20 reflected levorotary light C2 is further absorbed by the circular polarizing optical coating 7. Therefore, the cathode reflection interference of the intense light of the environment will be eliminated to enhance the contrast of the display under intense light of the environment. The dextrorotary light D emitted from the lighting layer 4 will not be 25 absorbed by the circular polarizing optical coating 7 and can totally penetrate through the circular polarized optical coating 7 to enhance the brightness of the display. Accordingly, the using efficiency of the energy

is increased and the contrast and brightness of the display are greatly enhanced.

The above embodiments are only used to illustrate the present invention, not intended to limit the scope thereof. Many modifications of the above embodiments can be made without departing from the spirit of the present invention.
